Laboratory Activity No. 8	
Converting TUI to GUI Programs	
Course Code: CPE103	Program: BSCPE
Course Title: Object-Oriented Programming	Date Performed: March 15, 2025
Section: CpE 1A	Date Submitted: March 15, 2025
Name: Junichiro H. Uy	Instructor: Maria Rizette M. Sayo
1 Objective(s)	

1. Objective(s):

This activity aims to convert a TUI program to GUI program with the Pycharm framework

2. Intended Learning Outcomes (ILOs):

The students should be able to:

- 2.1 Identify the main components in a GUI Application
- 2.2 Create a simple GUI Application that converts TUI program to GUI program

3. Discussion:

In general, programs consist of three components—input, processing, and output. In TUI programs, input is usually obtained from an input statement or by importing data from a file. Output is usually given by a print statement or stored in a file. When we convert a TUI program to a GUI program, we replace input and print statements with Label/Entry pairs. Processing data and inputting and outputting data to files works much the same in both types of programs. The primary difference is that the processing in GUI programs is usually triggered by an event

4. Materials and Equipment:

Desktop Computer with Anaconda Python or Pycharm Windows Operating System

5. Procedure:

1. Type these codes in Pycharm:

```
#TUI Form
def main():
    # Find the largest number among three numbers
    L = []
    num1 = eval(input("Enter the first number:"))
    L.append(num1)
    num2 = eval(input("Enter the second number:"))
    L.append(num2)
    num3 = eval(input("Enter the third number:"))
    L.append(num3)
    print("The largest number among the three is:",str(max(L)))
    main()
```

2. Run the program and observe the output.

```
Run: demo 8 × C:\Users\sayom\PycharmProjects\pythonProject1\venv\Scripts\python.exe "C:\Users\sayom\PycharmProjects\pythonProject1 \text{Enter the first number:} Enter the first number:
```

Figure 1. TUI form

```
Run: demo8 x

C:\Users\sayom\PycharmProjects\pythonProject1\venv\Scripts\python.exe "C:/Users/sayom/PycharmProjects/pythonProject1
Enter the first number: 22
Enter the second number: 22
Enter the third number: 23
Enter the third number: 24

Suppose the second number: 25

Suppose the second number: 25

Suppose the second number: 26

Suppose the second number: 27

Suppose
```

Figure 1(a) TUI form with three input numbers

```
Run: demo 8 × C:\Users\sayom\PycharmProjects\pythonProject1\venv\Scripts\python.exe "C:/Users/sayom/PycharmProjects/pythonProject1, Enter the first number: 52
Enter the second number: 5
Enter the third number: 5
The largest number among the three is: 123

Process finished with exit code 0
```

Figure 1(b) TUI form with output "The largest number among the three"

Method 1 above shows a TUI program and a possible output in Figures 1(a) and (b) while Figure 2 shows the output of the GUI program in Method 2.

5. Procedure:

```
Method 2
from tkinter import *
window = Tk()
window.title("Find the largest number")
window.geometry("400x300+20+10")
def findLargest():
  L = []
  L.append(eval(conOfent2.get()))
  L.append(eval(conOfent3.get()))
  L.append(eval(conOfent4.get()))
  conOfLargest.set(max(L))
lbl1 = Label(window, text = "The Program that Finds the Largest Number")
lbl1.grid(row=0, column=1, columnspan=2,sticky=EW)
lbl2 = Label(window,text = "Enter the first number:")
lbl2.grid(row=1, column = 0,sticky=W)
conOfent2 = StringVar()
ent2 = Entry(window,bd=3,textvariable=conOfent2)
ent2.grid(row=1, column = 1)
lbl3 = Label(window,text = "Enter the second number:")
lbl3.grid(row=2, column=0)
conOfent3=StringVar()
ent3 = Entry(window,bd=3,textvariable=conOfent3)
ent3.grid(row=2,column=1)
lbl4 = Label(window,text="Enter the third number:")
lbl4.grid(row=3,column =0, sticky=W)
conOfent4 = StringVar()
ent4 = Entry(window,bd=3,textvariable=conOfent4)
ent4.grid(row=3, column=1)
```

```
btn1 = Button(window,text = "Find the largest no.",command=findLargest)
btn1.grid(row=4, column = 1)
lbl5 = Label(window,text="The largest number:")
lbl5.grid(row=5,column=0,sticky=W)
conOfLargest = StringVar()
ent5 = Entry(window,bd=3,state="readonly",textvariable=conOfLargest)
ent5.grid(row=5,column=1)
mainloop()
```

Results 2

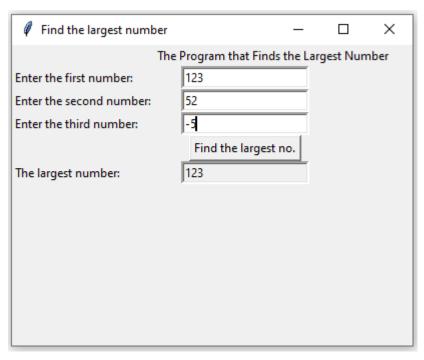

Figure 2. GUI program to find the largest number

Questions

- 1. What is TUI in Python?
- TUI stands for Text User Interface, allowing users to interact with applications through text-based commands in a terminal. It is commonly used for applications that require keyboard input and provide a text-based display.
- 2. How to make a TUI in Python?
- You can create a TUI in Python using libraries like curses, urwid, or blessed. A simple example involves using curses to display text and wait for user input in the terminal.
- 3. What is the difference between TUI and GUI?
- <u>TUI operates in a text-based environment and relies on keyboard input, making it lightweight and fast.</u> In contrast, GUI operates in a graphical environment with visual elements and mouse interaction, offering a more user-friendly experience but requiring more resources.

6. Supplementary Activity:

```
TUI Implementation
# Simple TUI Calculator
def add(a, b):
  return a + b
def subtract(a, b):
  return a - b
def multiply(a, b):
  return a * b
def divide(a, b):
  if b != 0:
     return a / b
  else:
     return "Error! Division by zero."
def main():
  print("Simple Calculator")
  print("Options:")
  print("1. Add")
  print("2. Subtract")
  print("3. Multiply")
  print("4. Divide")
  choice = input("Select operation (1/2/3/4): ")
  num1 = float(input("Enter first number: "))
  num2 = float(input("Enter second number: "))
  if choice == '1':
     print(f"{num1} + {num2} = {add(num1, num2)}")
  elif choice == '2':
     print(f"{num1} - {num2} = {subtract(num1, num2)}")
  elif choice == '3':
     print(f"{num1} * {num2} = {multiply(num1, num2)}")
  elif choice == '4':
```

```
print(f''(num1) / (num2) = {divide(num1, num2)}'')
  else:
     print("Invalid input.")
if name == " main ":
  main()
GUI Conversion of the Calculator:
import tkinter as tk
# Functions for calculation
def add():
  result.set(float(entry1.get()) + float(entry2.get()))
def subtract():
  result.set(float(entry1.get()) - float(entry2.get()))
def multiply():
  result.set(float(entry1.get()) * float(entry2.get()))
def divide():
  try:
     result.set(float(entry1.get()) / float(entry2.get()))
  except ZeroDivisionError:
     result.set("Error! Division by zero.")
# Create the main window
root = tk.Tk()
root.title("Simple Calculator")
# Create StringVar to hold the result
result = tk.StringVar()
# Create the layout
tk.Label(root, text="Enter first number:").grid(row=0, column=0)
entry1 = tk.Entry(root)
entry1.grid(row=0, column=1)
tk.Label(root, text="Enter second number:").grid(row=1, column=0)
entry2 = tk.Entry(root)
entry2.grid(row=1, column=1)
# Buttons for operations
tk.Button(root, text="Add", command=add).grid(row=2, column=0)
tk.Button(root, text="Subtract", command=subtract).grid(row=2, column=1)
tk.Button(root, text="Multiply", command=multiply).grid(row=3, column=0)
tk.Button(root, text="Divide", command=divide).grid(row=3, column=1)
# Label to show result
tk.Label(root, text="Result:").grid(row=4, column=0)
result label = tk.Label(root, textvariable=result)
result_label.grid(row=4, column=1)
# Start the main loop
root.mainloop()
```

Once you've successfully created the GUI version of the calculator, try adding the following features to enhance the program:

- 1. Clear Button: Add a button to clear the input fields and reset the result.
- 2. **History Feature**: Add a list or label to show the history of operations performed.
- 3. **Advanced Operations**: Implement additional operations such as square roots, powers, or trigonometric functions.
- 4. **Input Validation**: Add validation to ensure that the user only enters numeric values in the input fields.
- 5. **Styling**: Experiment with different styles (font sizes, button colors) to improve the appearance of the GUI.

6. Conclusion

creates a simple calculator using Python's Tkinter library. It allows users to perform basic math operations like addition, subtraction, multiplication, division, and some trigonometric functions. Users can enter two numbers, see the result, and view a history of their calculations. The app also handles errors if the input isn't a valid number, making it easy to use for anyone. Overall, it's a straightforward way to build a basic calculator with a graphical interface.
